

# 4. Data smoothing, Trend analysis and Harmonic analysis of data

Dr. Prasad Modak

Environmental Management Centre, Mumbai

# Why do data smoothing?

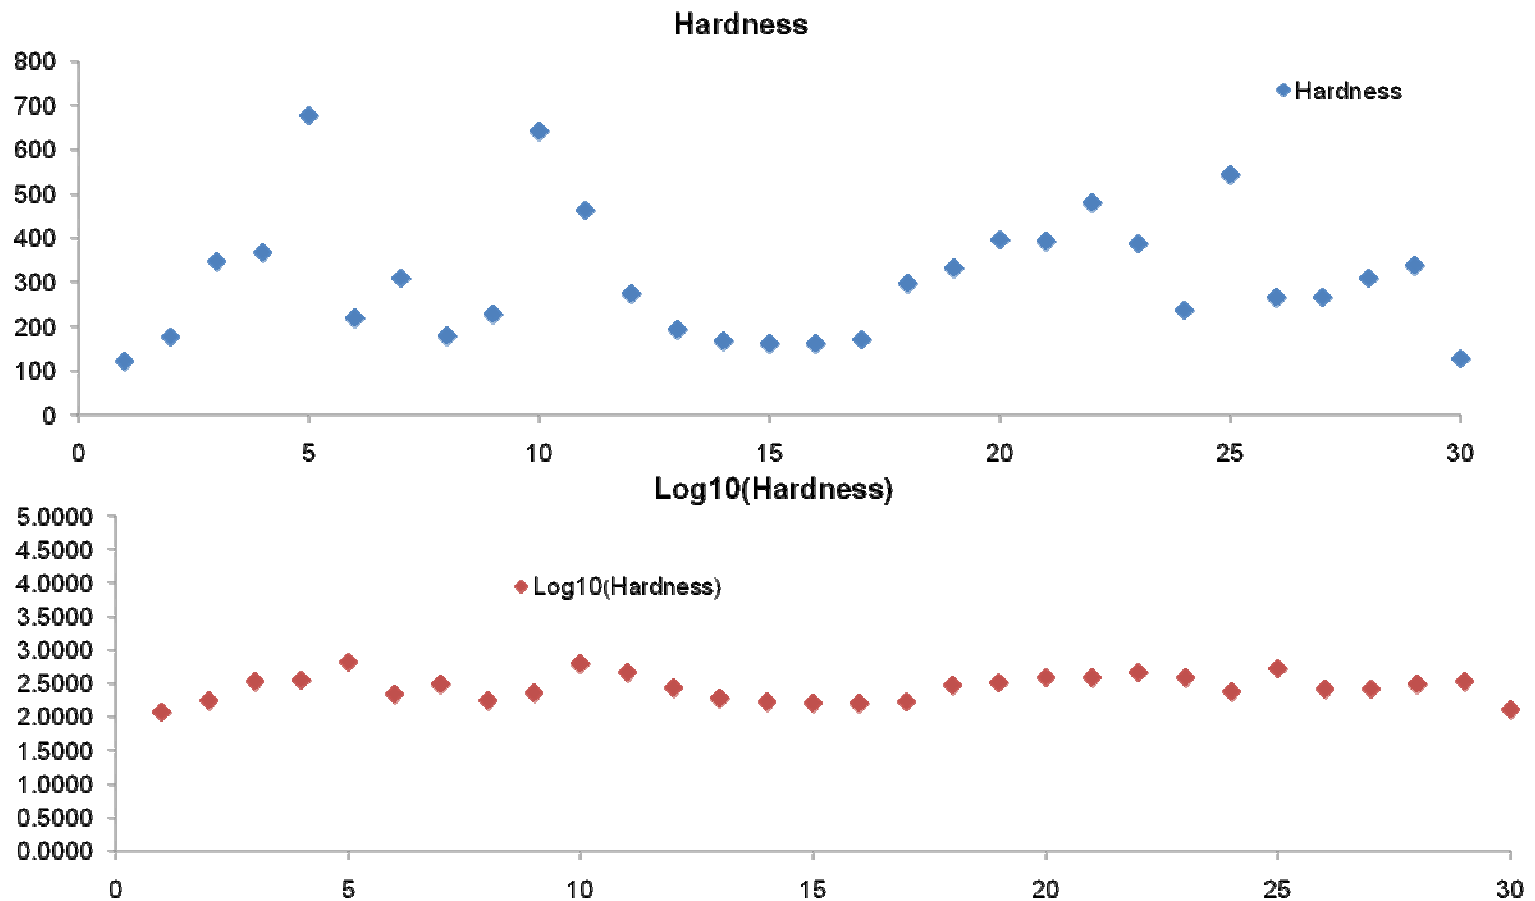

- Data smoothing is useful to reduce “noise” in the data.
- Minimizes the effects of cyclic trends (like seasonality) in data
- Reveal underlying patterns in the data
- When to data smoothing
  - Trend analysis of data
  - Long term reporting (annual report)

# How to do Data Smoothing?

- How to smooth data ?
  - Apply transformation to data (e.g. Log)
  - Use Moving Average (MA)
  - Use Exponentially Weighed Moving Average (EWMA)

# Using Log Scale

- Take  $\log_{10}(\text{number})$  of numbers
- Very effective for large numbers

# Using Moving Average

- MA is average of values for a defined period of time
- Simple average of the most recent 'k' data points
- Ignores the k-1<sup>th</sup> day from calculations
- Excellent way to suppress spikes and establish trends

$$\bar{y}_i(k) = \frac{1}{k} \sum_{j=i-k+1}^i y_j \quad \text{Where, } i = k, k+1, \dots, n$$

# Exponentially Weighted Moving Average

- EWMA gives more weightage to recent data than older data
- Influence of older data are essentially reduced in exponential manner during smoothing
- It has a feature  $\Phi$  , which denotes the “memory” of the system
- Lower  $\Phi$  denotes lower memory
- Equation is given by  $\bar{Z}_i = (1 - \Phi) \sum_{j=0}^{\infty} \Phi^j y_{i-j}$
- EWMA could be updated using:  $\bar{Z}_i = \Phi \bar{Z}_{i-1} + (1 - \Phi) y_i$

# Example of EWMA

# Trend Analysis (Spearman's Rho)

- Trend in environmental data
  - Seasonal
  - Non-seasonal
- Spearman's Rank Correlation Coefficient is often denoted by  $\rho$ .
- Spearman's Rho can be calculated and then compared to standard values to test the significance of the trend.
- Positive or negative  $\rho$  value indicate positive or negative trend
- Trend could be compared with standard values at a definite level of significance (90% or 95%) and N-2 degrees of freedom

# Spearman's Rho

- It is given by,

$$\rho = 1 - \frac{6 \sum D^2}{N(N^2 - 1)}$$

- D is difference between the serial and rank of a data point

- N is number of data point

- If ties exists between serial and rank

$$\rho = \frac{M - (D + T_x + T_y)}{\sqrt{(M - 2T_x)(M - 2T_y)}}$$

- Where

$$M = \frac{N^3 - N}{6} \quad T_x = \frac{t_x^3 - t_x}{12} \quad T_y = \frac{t_y^3 - t_y}{12}$$

- $t_x$  = Number of ties in ranks given to data
- $t_y$  = Number of ties in the time series

# Example Spearman's Rho

DO of Bhima River at Takli

| Month | 2009 | 2010 |
|-------|------|------|
| Jan   | 6.22 | 5.95 |
| Feb   | 6.12 | 6.56 |
| Mar   | 6.01 | 4.61 |
| Apr   | 4.2  | 5.94 |
| May   | 5.1  | 5.25 |
| Jun   | 5.2  | 6.9  |
| Jul   | 5.49 | 6.25 |

|       |      | D =        | <b>44</b> |      |

# Example ....contd..

|        |                 |
|--------|-----------------|
| N =    | 7               |
| 2009   |                 |
| $\rho$ | -1.63988        |
|        | <i>Negative</i> |

|       |   |
|-------|---|
| N-2 = | 5 |
|-------|---|

|        |                 |
|--------|-----------------|
| N =    | 7               |
| 2010   |                 |
| $\rho$ | -0.78274        |
|        | <i>Negative</i> |

|       |   |
|-------|---|
| N-2 = | 5 |
|-------|---|

Value 0.8 @95% confidence level  
*Significant*

Value 0.8 @95% confidence level  
*Insignificant*

- It can be inferred with 95% confidence that there was a significant downward trend in the DO concentration in Bhima River in the period 2009. This trend is however no longer significant in 2010.
- Discussion question: Why? What could be the reason?

# Harmonic Analysis

- Examines the periodicities or cyclic changes in the data
- Environmental data is prone to seasonal/annual cyclicity
- Harmonic Analysis is used to “filter” variation in data due to seasonal effects. Data is modeled by

$$f(x) = \bar{X} + \sum_{n=1}^{\infty} \left( A_n \cos \frac{2\pi nt}{N} + B_n \sin \frac{2\pi nt}{N} \right)$$

- Where 
$$A_n = \frac{2}{N} \sum_{i=1}^N X_i \cos \frac{2\pi nt}{N}$$
$$B_n = \frac{2}{N} \sum_{i=1}^N X_i \sin \frac{2\pi nt}{N}$$

$\bar{X}$  = Mean of the data; n = n<sup>th</sup> harmonic; t = Time from start, like the 2<sup>nd</sup> month will be 2 in monthly data; N = Total number of observations; T = The periodicity of the data, = n/N ; and; X<sub>i</sub> = Data corresponding to time t.

where

$\sigma^2$

## Harmonics ...contd...

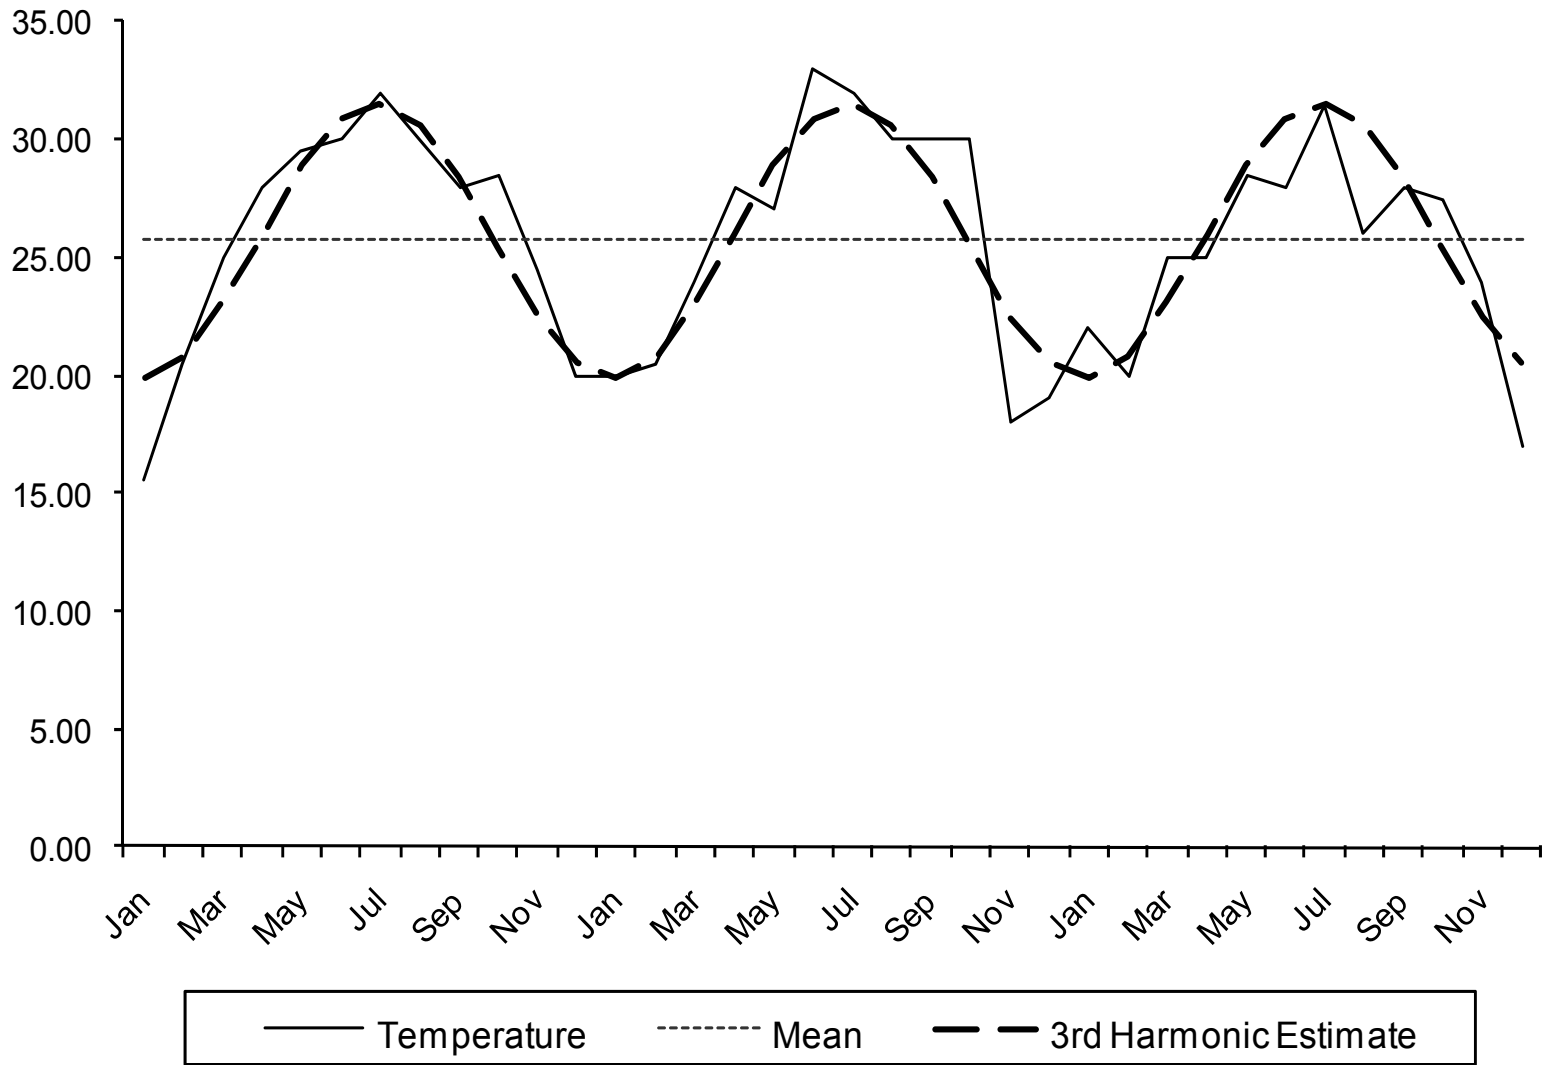

- In the harmonic series, if the calculation has been done for  $m$  harmonics, then sum up to  $n = 1$  to  $m$  instead of  $\infty$ .
- Variance in the observed record accounted for by each harmonic is given by the following formula

$$\sigma^2 = \frac{1}{2} \sum_{t=1}^N (A_n^2 + B_n^2)$$

$$p = \frac{\sigma_n^2}{\sigma^2}$$

- where  $\sigma^2$  is the total variance in the observed data.
- $p$  indicates which period is dominant in the data.
- The largest value of  $p$  will show the most dominant period.

# Example of Harmonic Analysis

# Additional Points

- Trend Mapping – How could this mapping system be used for “source diagnosis”?
- Can Model for Harmonic Analyses be used for predictions?
- What if harmonics for flow and concentration show different lags or contribution to Variance?
